Trading Intelligence System

Complete Feature Documentation · Trading Coach Presentation

Event-Aware Signals	Live Position Monitor	Multi-Ladder Execution	SL Cascade Automation
ATR-Dynamic Trailing	Kelly-Calibrated Sizing	MT5 Direct Execution	Signal Invalidation

Contents

1	Executive Summary	What DotVerse is and why it exists
2	The Signal Engine	14-indicator confluence gate, asset-specific calibration, ATR stops
3	Kelly-Calibrated Position Sizing	Half-Kelly from real backtest data, hard caps, plain-English output
4	Event-Aware Signal Intelligence	Economic calendar + crypto events checked at every signal
5	Live Position Event Monitor	60-second monitoring loop, active alerts, one-tap MT5 execution
6	Multi-Position Ladder Execution	10 simultaneous trades, per-position TP targets, preset strategies
7	Automated SL Cascade	TP1→Breakeven, TP2→TP1, TP3→TP2 — fully automated
8	ATR-Dynamic Trailing Stop	Trail distance tied to live ATR — not fixed pips
9	Signal Invalidation Detection	Mid-trade monitoring of confluence score and market structure
10	The Complete Automated Loop	End-to-end from signal to close with zero manual intervention
11	Competitive Advantage	What DotVerse does that no other retail tool offers

1 · Executive Summary

DotVerse is a complete, closed-loop trading intelligence system built for retail traders who want institutional-grade trade management without needing a trading desk. It does not send alerts and leave the trader to figure out the rest. It generates the signal, sizes the position, checks the macro calendar, places up to 10 simultaneous trades on MetaTrader 5, monitors every position live, and manages every exit automatically — breakeven moves, trailing stops, partial closes, SL ladder adjustments — all without the trader needing to be at a screen.

The founding principle is simple: the most common reason retail traders lose on technically correct setups is not bad analysis — it is bad execution. They enter at the wrong macro moment. They hold too large a position. They miss the partial close before a news event. They watch a profitable trade reverse because they had no automation on the stop. DotVerse eliminates every one of these failure modes with technology, not willpower.

65%	Minimum confluence for a signal to fire. 9 of 14 independent indicators must agree.
14	Indicators computed simultaneously per signal. Asset-specifically calibrated per class.
10	Maximum simultaneous positions per signal, each with its own TP target and risk allocation.
60s	Monitoring loop interval. Every live MT5 position checked against macro calendar every minute.
0	Manual actions required after trade placement. SL cascade, trailing, alerts — fully automated.
<15s	Time from signal generation to full AI macro verdict delivered on the signal card.

2 · The Signal Engine

The signal engine is not a wrapper around TradingView alerts. It is a custom quantitative confluence system that computes 14 independent technical indicators simultaneously and applies a hard 65% agreement gate before any signal is shown to the trader. This single architectural decision eliminates the noise signals that cause most retail signal services to underperform — a signal that fires on one indicator crossing a level is not a signal, it is a guess.

The 14 Indicators and What Each Measures

RSI (Relative Strength Index): Measures momentum — whether price is in an overbought or oversold condition. When RSI diverges from price (price makes a new high but RSI does not), it is one of the most reliable reversal signals in technical analysis. DotVerse computes RSI at asset-specific periods: Crypto 10, Forex/Stocks 14, Indices 21.

EMA Fast / EMA Slow / EMA 200: Three exponential moving averages computed simultaneously. The relationship between all three defines trend direction. Price above EMA 200 = long-term uptrend. EMA Fast above EMA Slow above EMA 200 = strong bull alignment (STRONG BULL). This is the most reliable trend filter in existence and requires no interpretation.

MACD (Moving Average Convergence Divergence): Detects momentum shift — when shorter-term momentum starts diverging from longer-term momentum, trend changes become probable. The histogram crossing zero is a high-confidence confirmation signal.

Bollinger Bands: Measure volatility compression and expansion. A squeeze (bands narrowing) typically precedes a large directional move. Price breaking outside the bands with volume confirmation is a breakout signal. The width tells you how much room the trade has before hitting resistance.

ATR (Average True Range — Wilder smoothed + 100-bar rolling mean): Measures actual market volatility. Used for stop loss sizing only — not as a directional signal. The smoothed ATR prevents stops being set inside normal daily noise, which is the single largest cause of premature stop-outs in retail trading.

Supertrend: A dynamic trend-following indicator that adapts to volatility using ATR. When Supertrend flips direction it signals a trend change. Unlike static indicators, it adjusts its sensitivity to current market conditions automatically.

Volume Ratio: Compares current volume to the 20-bar rolling average. A BUY signal with volume 1.5× above average has institutional backing. A BUY signal on below-average volume is a weak signal regardless of what other indicators show. Volume confirms or rejects every other signal.

Price Action Patterns: Swing highs, swing lows, higher highs, lower lows — the raw structure of the market. Trend analysis computed from actual price rather than mathematical derivatives. Confirms or conflicts with indicator readings.

HTF (Higher Timeframe) Bias: The signal is checked against the trend on the next higher timeframe. A BUY on the 4H timeframe is blocked if the 1D timeframe is in a strong downtrend. Trading with the higher timeframe trend dramatically improves win rates. Trading against it is the most common beginner mistake.

Confluence Score (Bull %, Bear %): The final output — a percentage vote across all indicators. 65%+ bullish = BUY. 65%+ bearish = SELL. Below 65% either direction = HOLD. No ambiguity. No interpretation required.

The 65% Gate — Why It Matters

Most signal services trigger on a single condition: RSI below 30, or MACD crossover, or price touching a support level. DotVerse requires all of the following to be simultaneously true before a BUY fires: momentum is bullish (RSI), trend is aligned (EMA stack), momentum is shifting (MACD), volatility supports the move (Bollinger), volume confirms it (Volume Ratio), and the higher timeframe agrees (HTF). Nine of fourteen must agree. This is the difference between a signal and a high-probability setup.

Asset-Specific Calibration

Asset Class	RSI Period	ATR Multiplier	EMA Fast/Slow	Why Different
Crypto	10	5×	7 / 14	Higher volatility. Faster RSI prevents lag on rapid moves.
Forex	14	4×	9 / 21	Standard — balanced sensitivity for 24h liquid markets.
Stocks	14	4×	9 / 21	Standard — matched to daily session volatility profiles.
Indices	21	3×	20 / 50	Slower RSI filters noise in broad market instruments.
Commodities	14	5×	9 / 21	Wide stops for commodity volatility spikes (oil, gold).

3 · Kelly-Calibrated Position Sizing

Incorrect position sizing is the single largest cause of account destruction in retail trading. Most traders size positions based on a fixed dollar amount, gut feel, or a percentage they read in a forum. Kelly Criterion is the mathematically proven formula for optimal position sizing derived from your actual edge. DotVerse computes it from real backtest data on every signal.

The Mathematics

The Kelly formula requires two inputs derived from actual trading history, not assumptions:

Win Rate (W)	The percentage of trades that close in profit on this asset, this timeframe, using these settings. Computed from the backtest every time a signal fires.
Payoff Ratio (R)	Average winning trade profit divided by average losing trade loss. A payoff ratio of 2.1 means wins are on average 2.1× larger than losses.
Full Kelly %	Formula: $W - ((1 - W) \div R)$. Example: 61% win rate, 2.1 payoff → $61\% - (39\% \div 2.1) = 42.4\%$. This is the theoretically optimal bet size.
Half-Kelly (Used)	Full Kelly $\div 2$. Universal conservative implementation. Maintains 75% of optimal growth rate while reducing drawdown by 50%. This is what professional quantitative funds use as their default.
Hard Cap (<100 trades)	Maximum 2.5% regardless of Kelly output. Fewer than 100 backtest trades means the sample size is insufficient for high confidence. The cap protects against overconfidence on thin data.
Hard Cap (100+ trades)	Maximum 5.0%. Sufficient sample size established. Cap prevents catastrophic sizing even on exceptionally strong historical edges.

Worked Example — BTC/USD 4H Signal

Backtest result: 61% win rate, 87 trades, average win \$310, average loss \$148. Payoff ratio = $310 \div 148 = 2.09$.

Full Kelly = $0.61 - (0.39 \div 2.09) = 0.61 - 0.187 = 42.3\%$

Half Kelly = $42.3\% \div 2 = 21.15\%$

Hard cap applied (87 trades, under 100 threshold): **2.5% maximum**

Result shown on signal card: **"Kelly sizing: 2.5% — based on 87-trade backtest, 61% win rate, 2.09 payoff ratio. Position size is capped because sample size is under 100 trades."**

The trader knows exactly why 2.5% was chosen and what the underlying data says.

What this means in practice: two traders with the same signal make completely different decisions. One risks 10% because "I feel confident." One uses DotVerse and risks 2.5% because the math says that is the optimal size for this edge. Over 100 trades the second trader's account grows on a mathematically optimal curve. The first trader's account experiences catastrophic drawdowns on the inevitable losing streaks.

4 · Event-Aware Signal Intelligence

The technical signal engine is mathematically blind to the world outside the candles. It does not know that US CPI releases in 6 hours. It does not know the Fed speaks tomorrow. It does not know ETH has a protocol upgrade in 4 days. These scheduled events cause technically valid setups to be stopped out — not because the analysis was wrong, but because the timing was wrong. DotVerse solves this by fetching live event data at the moment of every signal generation and incorporating it into the verdict.

Three Live Data Sources — Fetched at Every Analysis

Finnhub Economic Calendar: Covers every major global macro event with real-time data. US CPI, US NFP (Non-Farm Payrolls), Federal Reserve rate decisions and press conferences, ECB rate decisions, Bank of England decisions, Bank of Japan interventions, GDP releases, retail sales data, PMI readings, unemployment figures. Every event is impact-rated HIGH / MEDIUM / LOW based on historical market reaction. The feed is updated continuously as consensus estimates revise.

CoinMarketCal — Crypto Event Calendar: A specialist database maintained by a verified community of crypto analysts, covering events that technical analysis cannot detect: Protocol upgrades and hard forks (Ethereum upgrades, Bitcoin halving countdowns), Token unlock events (large amounts of previously locked tokens becoming tradeable, which creates massive sell pressure), Major exchange listings (new liquidity and retail access), Mainnet launches, Staking reward changes, Partnership announcements. These events move crypto markets by 15–40% and are completely invisible to any indicator.

Real-Time News Sentiment: Latest 24-hour headlines for the specific ticker being analysed, scored for positive/negative/neutral sentiment. A BUY signal on a stock with 8 negative headlines in the last 6 hours is a different risk profile from the same signal with neutral news.

How the AI Verdict Is Generated

All three data sources are fetched simultaneously in under one second. They are passed to a structured AI prompt alongside the full signal data (entry, SL, TP1/2/3, R:R, confidence, indicator breakdown). The AI is given one job: reason over the data provided, flag conflicts, and give a verdict. It cannot invent events. It cannot recall events from training memory. It can only reference events explicitly present in the calendar data it was given. This is the hallucination prevention mechanism — the AI is grounded in live data, not operating from memory.

EUR/USD BUY — EVENT RISK DETECTED

Technical setup: Entry 1.0842 | SL 1.0798 (44 pips) | TP1 1.0920 | Confluence 78% | CONFIRMED

EVENT RISK: US CPI releases in 8 hours (14:30 UTC, HIGH IMPACT). Consensus: 2.9%. Previous: 3.2%. EUR/USD historical average move on CPI: 85 pips. Your stop of 44 pips sits inside the expected volatility range. A surprise upside print (USD bullish) will stop this trade before the technical setup has time to play out.

Recommendation: Wait until 15:00 UTC post-release. If CPI is in-line or dovish, the BUY setup will likely still be valid and the entry can be taken with cleaner risk. If entering now is preferred, widen stop to 80 pips and reduce position size by 50%.

BTC/USD BUY — MACRO CLEAR

Technical setup: Entry 103,420 | SL 99,200 | TP1 108,600 | TP2 114,800 | TP3 122,000 | Confluence 81%

MACRO CLEAR: No high-impact events in the next 48 hours for BTC/USD. Next scheduled: FOMC minutes release Thursday (MEDIUM impact — typically 30-50 pip equivalent on BTC). Crypto event calendar: no token unlocks or protocol events in the next 7 days. News sentiment: neutral-positive (3 positive headlines, 1 neutral, 0 negative in last 24 hours).

Verdict: PROCEED — setup is clean. Kelly sizing: 2.5%. Full position approved.

The event check adds under 2 seconds to the total signal generation time. The trader receives a complete verdict — technical analysis + macro context + plain-English recommendation — on a single screen before committing any capital.

5 · Live Position Event Monitor

Pre-entry warnings protect traders before they commit capital. But what about positions already open when a macro event is scheduled? DotVerse runs a background monitoring loop every 60 seconds that checks every live MT5 position against the economic calendar. When a conflict is detected — an event approaching with the potential to reverse a profitable position — an active alert fires with specific numbers and one-tap execution buttons.

What the 60-Second Loop Checks for Every Position

Current profit in pips and as a percentage toward TP1: Calculates in real time from the live MT5 price feed pushed by the EA every 5 seconds.

Distance from current price to stop loss: How many pips are left before the stop is hit. Used to determine whether an event's expected volatility could reach the stop.

Next HIGH or MEDIUM impact event for this asset in the next 48 hours: Fetched from the economic calendar. Matched to the position's instrument (EUR/USD events = ECB, Fed, US data. BTC/USD events = crypto calendar).

Historical average move for that event on that instrument: For example, EUR/USD average move on US CPI over the last 20 CPI releases. This tells the system whether the event's expected volatility is larger or smaller than the current stop distance.

Confluence score comparison: Current confluence on this instrument compared to the confluence at entry. If the score has dropped below 50% since entry, the original setup basis has weakened.

ATR comparison: Current ATR versus ATR at entry time. If ATR has expanded significantly, the original TP targets may be conservative — the market has more room than originally calculated.

The Active Alert — What the Trader Receives

LIVE ALERT — EUR/USD BUY · Ticket #1847293

Opened Monday at 1.0842. Currently at 1.0887 — **+45 pips (+102% toward TP1)**.

US CPI releases in 14 hours (Thursday 14:30 UTC, HIGH IMPACT). EUR/USD average move on CPI: 85 pips. Your stop is at 1.0798 — 89 pips below current price. The expected event volatility (85 pips) is nearly equal to your stop distance. A surprise print in either direction has a high probability of reaching your stop before price has time to recover to TP1.

You have two options:

Option A — Protect profit now: Close 50% at +45 pips. Move remaining stop to entry price (1.0842, breakeven). Worst case if CPI surprises: remaining half closes at zero loss. You bank the partial profit. Best case: CPI is in-line, price continues, remaining half reaches TP1.

Option B — Hold full position: Stop remains at 1.0798. Full risk if CPI surprises. Only choose this if you have high conviction the number will match or disappoint consensus.

[Close 50% + Move to Breakeven] [Keep Full Position — I understand the risk]

Both buttons execute directly on the live MT5 account. "Close 50% + Move to Breakeven" sends a partial close order to MT5 and a modify order to move the stop simultaneously. The trader does not need to open MT5. They do not need to calculate the partial lot size. They tap one button and the system handles the execution.

Two Additional Mid-Trade Alerts**Signal Invalidation Alert**

If the confluence score on a live position's instrument drops below 50% — meaning the original setup has structurally weakened — DotVerse alerts: **"Setup Weakening — EUR/USD BUY: Confluence at entry was 78%. Current confluence is 44%. EMA 9 has crossed below EMA 21. The original BUY basis is no longer confirmed. You are +12 pips. Recommended action: tighten stop to +8 pips to protect partial profit while waiting for re-confirmation."**

This catches the scenario where market structure changes mid-trade. The position was valid when entered. It may no longer be valid now. The system detects this before the trader loses their profit.

ATR Expansion Alert — More Room Than Originally Calculated

If ATR expands significantly after entry (volatility surge following news or breakout), the original TP targets — set at entry ATR — may be too conservative.

Alert: **"Volatility Expanded — BTC/USD BUY: ATR at entry was 42 pips. Current ATR is 78 pips. Your TP3 at 122,000 was calibrated for 42-pip ATR conditions. In current volatility, a full 4× ATR target would be 124,640. The trade has more room than originally calculated. Consider letting the trail-only position run past TP3."**

6 · Multi-Position Ladder Execution

This is the most powerful execution feature in DotVerse. Instead of entering one position and manually managing partial closes as TP levels are hit, DotVerse opens up to 10 simultaneous positions at the exact same entry price. Each position has its own risk allocation and its own assigned TP target. Each position has a clear mission. Together they capture the full range of possible outcomes from a single signal — from the quickest TP1 harvest to the full extended trend move.

The Core Concept — Why Multiple Positions Instead of One?

Why not just enter one position and close 50% manually at TP1?

Three reasons. First, manual partial closes require the trader to be at a screen at exactly the right moment. Markets do not wait. TP1 can be hit and reversed in seconds during volatile conditions. Second, on MT5 a separate position ticket is a clean, independent trade. It has its own SL, its own TP, and its own automation. When its TP is hit, MT5 closes it automatically without any human action. Third, the SL cascade automation (detailed in Feature 7) fires when a TP level is reached across ALL remaining open positions simultaneously. With one position, manual management is required at every step. With 10 separate positions, the entire trade lifecycle is automated.

Do all positions use the same stop loss?

Yes. All positions share the same entry price and the same SL price. The stop is set by the ATR-based signal engine and is the same for every position in the ladder. Only the TP target and the risk % allocation differ per position. This means if the SL is hit, all positions close at the same price simultaneously — total loss equals the sum of all risk % allocations, which is always within the Kelly-defined limit.

BTC/USD 10-Position Ladder — Full Example

Entry: 103,420 | SL: 99,200 | TP1: 108,600 | TP2: 114,800 | TP3: 122,000 | Account: \$10,000

#	Risk %	\$at Risk	Target	Max Loss	Profit if Hit	R:R	Mission
1	0.3 %	\$30	TP1 108,600	-\$30	+\$107	3.6 x	Fast harvest — smallest risk on easiest target
2	0.5 %	\$50	TP1 108,600	-\$50	+\$178	3.6 x	Second TP1 harvest — more size
3	0.7 %	\$70	TP1 108,600	-\$70	+\$249	3.6 x	Third TP1 — scale into the most likely outcome
4	0.8 %	\$80	TP2 114,800	-\$80	+\$567	7.1 x	Medium run — holds past TP1
5	1.0 %	\$100	TP2 114,800	-\$100	+\$709	7.1 x	Core TP2 allocation — highest probability R:R
6	1.0 %	\$100	TP2 114,800	-\$100	+\$709	7.1 x	Second TP2 — equal weight on main target

7	0.8 %	\$80	TP3 122,000	-\$80	+\$1,330	16.6x	Full trend rider — significant move needed
8	0.7 %	\$70	TP3 122,000	-\$70	+\$1,164	16.6x	Second TP3 — rides the full move
9	0.5 %	\$50	TP3 122,000	-\$50	+\$831	16.6x	Third TP3 — extended trend
10	0.3 %	\$30	Trail — no TP	-\$30	Open	Open	Catches move past TP3. Trail-only.

Total max loss (all 10 positions hit SL simultaneously):	-\$660 (6.6% of \$10,000 account)
Profit if only TP1 is reached (positions 1–3 close, 4–10 → breakeven):	+\$534 with ZERO remaining risk
Profit if TP1 + TP2 reached (6 positions closed, 4 remain at TP1 stop):	+\$2,548 locked — running in pure profit
Profit if all TPs reached (positions 1–9 closed, position 10 trailing):	+\$5,843 minimum — position 10 still open

7 · Automated SL Cascade System

The SL cascade is the trade management automation that runs without any human action after the ladder is placed. As each TP level is hit, MT5 automatically modifies the stop loss on all remaining open positions to lock in an increasing amount of profit. By the time TP3 is reached, every remaining position is running with zero loss possible — only upside remains. The trader can be asleep and the system manages every step.

Trigger	Positions That Close	Automated SL Action	Risk After Action	Telegram Alert
TP1 hit at 108,600	Positions 1, 2, 3 close automatically at TP1 price via MT5 take profit order	SL on ALL remaining positions (4–10) moves to entry price 103,420 — breakeven	ZERO — positions 4–10 cannot lose. Worst case closes at zero profit.	Sent instantly: "TP1 hit — SL moved to breakeven on 7 positions. +\$534 banked."
TP2 hit at 114,800	Positions 4, 5, 6 close automatically at TP2 price via MT5 take profit order	SL on remaining positions (7, 8, 9, 10) moves to TP1 price 108,600 — locking TP1 profit	Positions 7–10 cannot close for less than TP1 gain. Guaranteed profit.	Sent instantly: "TP2 hit — SL at TP1. +\$2,548 total locked. 4 positions running."
TP3 hit at 122,000	Positions 7, 8, 9 close at TP3 price. Position 10 (trail-only) continues.	Position 10 trailing stop tightens to current ATR — rides any extension past TP3	Position 10 stop is above TP2. Only upside remaining on the final position.	Sent: "TP3 hit — +\$5,843 locked. Position 10 running with ATR trail."
SL hit (any point)	All open positions close at SL price simultaneously	No SL action — trade is closed	Total loss = sum of all risk % on open positions at time of SL hit	Sent: "SL hit on BTC/USD. Total loss: -\$X. System monitoring for next signal."

The cascade is triggered by the EA sending a level alert to DotVerse when a TP price is hit. DotVerse immediately queues a modify order for every open position on that symbol. The EA picks up the modify order on its next 5-second poll and executes on MT5. The entire process — from TP hit to SL modified on all remaining positions — completes within 5–10 seconds with no manual action.

What happens if the trader is asleep when TP1 is hit at 3am?

Nothing changes. The EA is running on the MT5 terminal continuously. When TP1 price is hit, MT5 closes positions 1, 2, and 3 automatically (their take profit orders are set at TP1 price). The EA detects the close, sends a level alert to DotVerse. DotVerse queues the SL modify. The EA picks it up within 5 seconds and modifies the SL on all remaining positions to breakeven. A Telegram message is sent to the trader's phone. They wake up to a message saying TP1 was hit, profit was banked, and the remaining positions are now at zero risk. Total human involvement required: none.

8 · ATR-Dynamic Trailing Stop

The final position in every ladder (Position 10) does not have a fixed TP. Its job is to ride the trend as far as it goes, with a trailing stop that adjusts automatically to live market conditions. The traditional approach — a fixed pip trailing stop — is fundamentally broken. DotVerse replaces it with ATR-dynamic trailing.

What is wrong with a fixed pip trailing stop?

A fixed 50-pip trailing stop treats every market condition identically. On a quiet Tuesday when BTC is moving 200 pips per day, a 50-pip trail is appropriate — it gives the trade room to breathe. On a CPI release day when BTC moves 800 pips in an hour, a 50-pip trail is hit by normal volatility noise before the real directional move plays out. The same problem in reverse: on a low-volatility week a 50-pip trail is too wide and gives back too much profit before closing. Fixed numbers disconnect the trailing stop from the market's actual behaviour.

How ATR-Dynamic Trailing Works

ATR measures actual market volatility — specifically, the average price range per bar over the last N bars. When the market is quiet, ATR is small. When the market is active, ATR is large. It is a live, continuously updating measure of how much the market is moving right now.

The trail distance is set to 1.0× current ATR. On a quiet day ATR might be 120 pips — trail is 120 pips. On a CPI day ATR might be 320 pips — trail is 320 pips. The trail automatically adapts to conditions without any trader input.

DotVerse recalculates the ATR every 60 seconds from the watch job's live data. If ATR changes by more than 10% from the previous calculation, a modify order is queued to MT5 updating the trailing stop distance. The EA executes it within 5 seconds.

The trail only moves in the direction of profit. If ATR expands after a big move (volatility spike), the trail widens — giving the trade more room. If ATR contracts (market quiets down), the trail tightens — locking profit faster. It behaves exactly as a professional trader managing the position manually would.

No trader input is required. The trail is activated automatically when Position 10 is submitted. The only decision the trader makes is whether to use Conservative (0.75× ATR, tighter) or Standard (1.0× ATR) trail.

ATR Trailing in Practice — BTC/USD

BTC/USD position open at 103,420. Currently at 118,200 (post TP3).

Monday morning ATR (quiet weekend): 480 pips. Trail set at 480 pips → stop at 117,720.

Tuesday: US macro data causes a spike. BTC reaches 122,000. ATR recalculates to 890 pips. Trail updates automatically → stop at 121,110.

Wednesday: Volatility subsides. BTC consolidates at 121,500. ATR recalculates to 560 pips. Trail tightens → stop at 120,940.

Thursday: BTC pulls back to 121,200. Stop not hit — still running.

Friday: BTC reaches 125,000. ATR 620 pips. Stop at 124,380.

Monday: BTC reverses to 124,000. Stop at 124,380 → **Position closes at 124,380.**

A fixed 50-pip trail would have closed this position on the Tuesday volatility spike. ATR-dynamic trailing captured an additional 5,960 pips (from TP3 at 122,000 to close at 124,380).

9 · Signal Invalidation Detection

A trade that was valid when entered can become invalid during its lifetime. Market structure changes. The confluence that drove the original signal reverses. Most trading systems are blind to this — they set a stop and walk away. DotVerse's 60-second watch loop continuously re-evaluates the original signal's basis while the trade is live and alerts when the setup degrades.

What Triggers a Signal Invalidation Alert

Confluence score drop below 50%: The watch job re-analyses the instrument every 60 seconds. If bull% falls from the entry value (e.g., 78%) to below 50%, the original setup basis has structurally weakened. This is not normal oscillation — it means the majority of indicators have flipped.

EMA cross reversal: If EMA Fast crosses below EMA Slow on a BUY trade, the core trend indicator that supported the entry has reversed. This is a significant structural change, not noise.

Supertrend flip: Supertrend changing direction mid-trade is a high-reliability reversal signal. Combined with confluence drop, it is the strongest mid-trade warning the system can generate.

HTF bias change: If the higher timeframe trend — which was aligned at entry — reverses, the trade is now moving against the longer-term direction. This is the scenario most likely to result in a sustained move against the position.

Signal Invalidation Alert

■ SETUP WEAKENING — EUR/USD BUY · Ticket #1847293

Entry confluence: 78% bullish (11/14 indicators). Current confluence: 43% bullish (6/14 indicators).

EMA 9 has crossed below EMA 21 — trend alignment lost.

Supertrend has flipped to bearish on the last closed candle.

You are currently +12 pips from entry. The original BUY basis is no longer confirmed by the indicator set.

Recommendation: Tighten stop to +8 pips (above entry, locking partial profit) and wait for re-confirmation. If confluence does not recover above 60% on the next 2 candles, consider closing the position to preserve profit. The setup will re-fire as a new signal if conditions re-establish.

[Tighten Stop to +8 Pips] [Keep Original Stop — I Will Monitor]

10 · The Complete Automated Loop

Every feature described in this document is a connected node in a single closed-loop system. The signal feeds the sizer. The sizer feeds the event check. The event check informs the execution decision. The ladder executes on MT5. MT5 reports back to DotVerse. DotVerse monitors and manages every position through to final close. The trader makes one decision — Place Trade — and the system handles everything from that moment forward.

01**SIGNAL FIRES**

Confluence gate reaches 65%+ on 14 indicators. Asset-specific parameters applied. ATR-smoothed stop calculated. Net R:R computed after 0.2% fee deduction. Backtest runs in background — win rate and payoff ratio computed for Kelly sizing.

02**MACRO CHECK**

Economic calendar fetched (Finnhub). Crypto events fetched (CoinMarketCal). News sentiment fetched. AI generates MACRO CLEAR / CAUTION / HIGH RISK verdict with plain-English explanation. Total time: under 2 seconds. Result appears inline on signal card.

03**KELLY SIZING**

Half-Kelly computed from backtest win rate and payoff ratio. Hard cap applied (2.5% under 100 trades, 5.0% over 100 trades). Ladder rows pre-populated with Kelly-derived allocations. Trader can adjust or accept preset (Conservative / Balanced / Conviction).

04**LADDER REVIEW**

Trader sees: Signal card with entry/SL/TP1/2/3, Kelly size, macro verdict, and ladder configuration. All information needed to make the trade decision is on one screen. Trader reviews and clicks Submit All to MT5.

05**MT5 EXECUTION**

Up to 10 simultaneous market orders submitted via /api/mt5/order. EA picks up orders on next 5-second poll. All positions open at the same entry price. Each position has its specific TP set as the MT5 take profit level. Trader is sent to the Act tab to see positions populate live.

06**60s MONITOR LOOP**

Background job runs every 60 seconds. Checks all live positions against event calendar, confluence score, ATR. Fires alerts when action is needed. Trader receives specific recommendations with one-tap execution buttons for partial close, breakeven, or stop tighten.

07**SL CASCADE**

As each TP is hit, MT5 closes the relevant positions automatically. Level alert fires to DotVerse. DotVerse immediately queues SL modify orders for all remaining positions. EA executes within 5 seconds. Telegram fires at every stage. Trader is notified without needing to watch the screen.

08**ATR TRAILING**

Position 10 (trail-only) rides the extended move. Trail distance recalculated every 60 seconds from live ATR. Modify order queued to MT5 when ATR changes by more than 10%. Position closes automatically when trail is hit. No TP ceiling — captures the full move.

09**TRADE CLOSE**

All positions closed — either by TP automation, SL hit, trail, or manual close. Result logged to portfolio table. Win rate and payoff ratio updated for this asset/timeframe. Kelly recalibrates for next signal. Signal history updated.

10**NEXT SIGNAL**

Watch job continues scanning watched instruments every 60 seconds. When confluence reaches 65% again on this or any other instrument, the entire loop restarts. The system never stops working.

11 · Competitive Advantage

The trading tools available to retail traders today fall into two inadequate categories. Simple signal services tell you to buy or sell with no context, no sizing, no event awareness, and no trade management. Complex professional platforms require months of training and assume deep market knowledge. DotVerse occupies a category that does not currently exist.

Capability	TradingView Alerts	Standard EA/Bot	Signal Service	DOTVERSE
Confluence-gated signals (65% threshold)	✗	Varies	✗	✓

Telegram alerts for every automated action	Paid	Varies	Varies	✓
Direct MT5 execution from web dashboard	✗	N/A	✗	✓
No manual screen monitoring required	✗	Partial	✗	✓

DotVerse is not a signal app with an AI badge. It is the first complete closed-loop trading system built for retail traders — running the full stack from signal to close, automated, explained, and connected.
